CMOS 512-bit SERIAL E²PROM

S-2900A

The S-2900A is a wide operating voltage range, low power consumption 512-bit E^2 PROM. The organization is 64-word × 8-bit, and can be read or written serially. It is easily interfaced with a serial port because the instruction is composed of eight-bit units.

Features

- Operating voltage
 - Read : 1.5 to 5.5 V
 - Write : 2.7 to 5.5 V
- Power consumption

Standby : 1 µA max.

- Read : 1.4 mA max. (V_{CC}=5.5 V) 0.4 mA max. (V_{CC}=1.5 V)
- 500 kHz (V_{CC}=2.7 V to 4.5 V)
- $100 \text{ kHz} (V_{CC}=1.5 \text{ V to } 2.7 \text{ V})$ • Memory configuration 512 bits (64-word \times 8-bit)

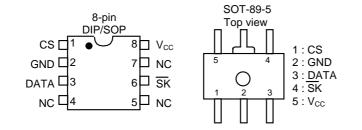

2 MHz (V_{CC}=4.5 V to 5.5 V)

Byte writing/Byte reading

• Operating Frequency

- Data retention: 10 years
- Package : 8-pin DIP/SOP
 - SOT-89-5 Bare chip

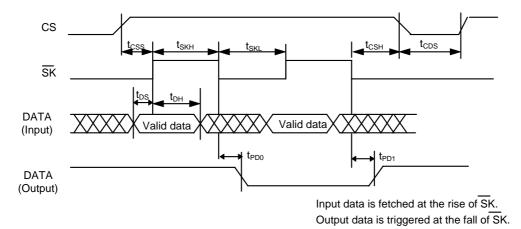

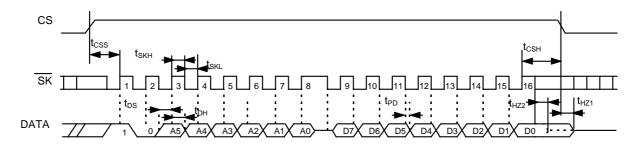

Figure 3 Timing chart

Operation

(1) Read (READ) mode

After changing CS from "L" to "H", this mode inputs the op code and address into DATA, synchronized with the rise of \overline{SK} . When A0 is input at the rise of the eighth \overline{SK} clock cycle, eight-bit data in the specified address is output from the DATA pin, synchronized with the falling of \overline{SK} .

The DATA pin changes to high impedance after CS changes to "L".

(2) Write (PROGRAM) mode

After changing CS from "L" to "H", this mode inputs the op code, address, and data (eight -bit) into DATA, synchronized with the rise of SK. After data is input, by changing CS from "H" to "L" again, data is written to the chip (the write operation). The write operation time is decided by the timer inside of the IC (10 ms max.).

After the write operation, The S-2900A is automatically in program disable mode. Therefore, the S-2900A must be in program enable mode through executing the PEN instruction before the write operation.

For confirming completion of the write operation, check the status read mode described later.

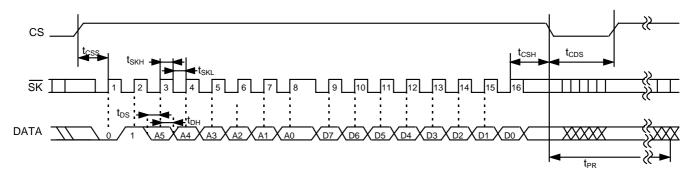

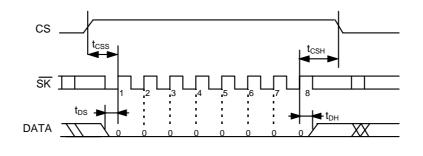

Figure 5

(3) Program enable (PEN) mode

After being in program enable mode through executing the PEN instruction, data can be written (programmed). Before executing a program instruction, the PEN instruction must be executed.

After changing CS from "L" to "H", this mode inputs the op code and address " 00_{H} " into DATA, synchronized with the rise of \overline{SK} . When instruction is received at the rise of the eighth \overline{SK} clock cycle, the S-2900A is in program enable mode.

(4) Status read (STRD) mode

STRD confirms whether or not the write operation has been completed. During the write (Busy) operation, low level is output from DATA, and after completing the write operation (Ready status), high level is output. After changing CS from "L" to "H", this mode inputs the op code and address " $3F_{H}$ " into DATA, synchronized with the rise of SK. From the falling edge of the eighth SK clock cycle, the S-2900A outputs the write operation status.

Question:

What about the reliability and quality of the EEPROM?

Answer:

1. The EEPROM must have a quality that is "special in a sense" and that differs from that of the other ICs.

<What is this special quality?>

(1) Number of possible rewrites: 105 or 106

A specified minimum number of data rewrites must be assured.

(2) Data retention: 10 years

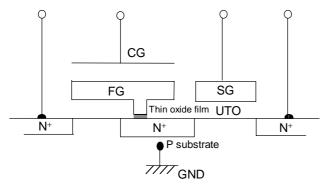

It must be ensured that written data ('1' and '0') will be stored for at least 10 years.

Ensuring (1) and (2) is very difficult in a technical sense, as well as in the sense that high quality must

- be maintained despite the need for mass production.
- 2. Why this guarantee is technically difficult

As shown in the figure below, the EEPROM functions as a non-volatile memory by holding charges in FG.

Source electrode Control gate electrode Select gate electrode Drain electrode

[Data rewrite]

<u>Data rewrite</u> refers to the injection or removal of electrons into or from the FG. In this process, electrons pass through a thin oxide film (UTO). The oxide film inherently acts as an insulator, but in this case the film conducts electricity (electrons are transferred).

[Data retention]

<u>Data retention</u> refers to the prevention of leakage of electrons stored in the FG. This must be assured for at least 10 years.

To meet the above stated contradictory properties, high-quality thin oxide films (UTO) must be manufactured. Such UTOs are very thin (on the order of 10 nm), and stably manufacturing them requires a very difficult technique.

Question:

What about the distribution of application notes, usage notes, and malfunctions?

Answer:

Distribution of application notes

All EEPROMS, including ours, may malfunction (false-writes may occur) due to an "operation in a lowvoltage region upon power-on/off" or "improper recognition of a command due to a noise signal." This defect is particularly common in the voltage region of the microcomputer transmitting commands to the EEPROM, where the voltage is lower than the lowest operating voltage of the microcomputer.

To prevent this defect, usage notes have been prepared for the EEPROM.

- S-93C series, S29 series
- S-24CxxA series
- S-24CxxB series

Question:

What are some applications of the serial EEPROM?

Answer:

1. Applications of the EEPROM

The applications of the EEPROM can be roughly divided into the following types:

- Tuning memory, mode setting, ID codes: Arbitrary data can easily be rewritten and data can be retained during power-off.
- Replacement of a DIP switch (from a mechanical to an electronic switch): User costs are substantially reduced.
- Adjustment data for IC elements and other electronics: The accuracy of final products is increased. Adjustments, which had been performed manually, can be automated.
- 2. Specific examples of applications

Based on the above applications, general examples are shown below. Basically, the EEPROM (a non-volatile memory) is useful for electronic applications.

[Television]	TV channel memory, screen setting data, data backup during power-off S-24C series
[Video]	VTR channel memory, program reservation data, image-quality adjustment data, data backup during power-off S-93Cx6A, S-29xx0A, S-24C series
[White goods]	Maintenance data, adjustment data S-93Cx6A, S-29xx0A, S-24C series
[Vehicle-mounted] Troubleshooting data, maintenance data, adjustment data: Air bags, ABS, distance meters S-93Cx6A, S-29xx0A, S-24C series
[Printers]	Printer maintenance data S-93Cx6A, S-29xx0A, S-24C series

[Modems]	Replacement of DIP switches, software (firmware) data S-93Cx6A, S-29xx0A, S-24C series
[Mobile telephone	 Personal ID, telephone-number data, address data, adjustment data S-24C series
[Pagers]	Personal ID, telephone-number data, address data S-93Cx6A, S-29Z series, S-24C series
[PC cards]	LAN cards and modem cards, replacement of dip switches, software data S-93C46A, S-29, S-24C series

Question:

What about the basic terms (verify, ready/busy function)?

Answer:

Verify, ready/busy (R/B) function

This is a function to find out about an actual write operation (time). There are two methods, a "monitoring method based on the output condition of the DO pin" and a "method for monitoring the output condition of the Ready/Busy pin." This function eliminates the need to wait 10 ms for writing to be completed, thereby minimizing the write time according to the performance of the IC (performance value: 4 ms to 5 ms; 1 ms is ensured for the S-24C series).

(Note) Note that this differs from a normal verify function, which checks written data for errors.

Question:

What about the basic term (page write)?

Answer:

Page write S-24C series

Writing to memory is normally executed in addresses. With the page write function, however, writing can be executed in pages (multiple addresses). This function can improve the efficiency of write commands and reduce writing time.

Ex.:S-24C04B (4 K = 512 addresses x 8 bits) 16-byte page write function

Writing in addresses: A write time of 10 msec. x 512 = 5.1 sec. is required.

Page write: 10 msec. x 512 / 16 = 320 msec.

However, compatibility with products from other companies must be confirmed.

Question:

What about the basic terms (Test pin, ORG pin)

Answer:

TEST pin

This is an input pin used to enter a test mode when tests are conducted during an SII inspection process. This information is not provided to users. It can be used with a GND or Vcc connection, or in an open state (see note). This is important in maintaining compatibility with the pin layouts of other companies. Some users fear that the test mode may be inadvertently entered during operation, but such fears are unnecessary, as a potential of at least 10 V must be constantly supplied to enter the test mode.

(Note) Since the TEST pin has a C-MOS input structure, the GND or Vcc connection is most suited for this pin.

ORG (Organization) pin

Input pin used to specify a memory configuration. A normal memory has a "16 bit/1 address" data configuration and includes no ORG pin. Competing manufacturers, however, have released products that enable data to be switched between "x16" and "x8" using "H" or "L" of the ORG pin. Since this function is provided for the 93C series of the NS code, there is a compatibility problem. SII has not yet released products featuring this function.

Question:

Malfunction (false-write, illegal data)

Answer:

[Malfunction of the EEPROM] (key words: false-store(illegal data)

The EEPROM may malfunction (false-store) due to power-on/off or noise from the microcomputer. The

defect rate, however, is on the order of ppm. Even though, this could be a serious problem for the users

and to the applications.

- This problem essentially results from users' design techniques, but the manufacturer should make efforts to prevent this defect. As the unit price continuously decreases, this is particularly important in discriminating us from our competitors.
- Improving the business techniques of the manufacturer
 Malfunction basically results from a user's inappropriate operation, so the user is the responsible party. We, however, must bear responsibility for defects in the IC. Thus, the best action to take depends on whether the user or SII is responsible for the defect. In practice, however, it is difficult to determine from a user's claim or inquiry, or through an agent, who is responsible for a defect.

In such a case, inform the Business Techniques section of the situation as soon as possible. In addition,

see FAQ on other "malfunctions" for technical information.

Question:

Power-on clear in S-93CxxA, S-29xxxA, notes for power-on (malfunction)

Answer:

1. This IC series has a built-in power-on clear circuit.

This circuit instantly initializes the EEPROM when the power voltage is activated. Since malfunction may occur if initialization has not been completed normally, the conditions specified below are required to activate the power voltage in order to operate the power-on clear circuit normally.

- 2. Notes on power-on
- ① Method for activating the power voltage

As shown in Fig. 1, activate the power voltage starting from a maximum of 0.2 V so that the power voltage reaches the operating value within the time specified as tRISE. If the operating power voltage is, for example, 5.0 V, tRISE = 200 ms, as shown in Fig. 2. Thus, the power voltage must be activated within 200 ms.

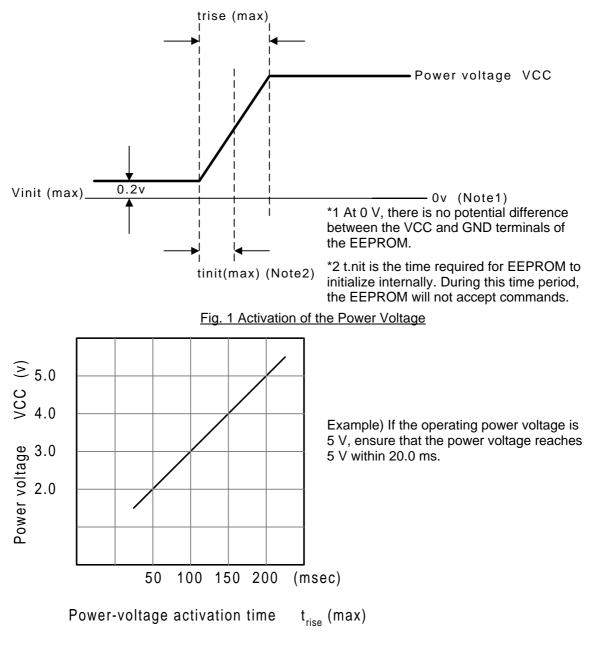

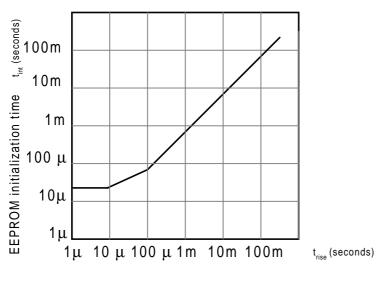

Fig. 2 Maximum power-voltage activation time

② Initialize time tinit

The EEPROM is instantly initialized when the power voltage is activated.

Since the EEPROM does not accept commands during initialization, the transmission of commands to the EEPROM must be started after this initialization time period.

Fig. 3 shows the time required to initialize the EEPROM.

Power-voltage activation time

Fig. 3 EEPROM initialization time

When the power-on clear circuit has finished initialization normally, the EEPROM enters a program-

disabled state. If the power-on clear circuit does not operate, the following situation is likely:

 In some cases, a previously entered command has been enabled. If, for example, a programenabled command has been enabled and the input terminal mistakenly recognizes a write command due to extraneous noise while the next command is being entered, writing may be executed.

The following may prevent the power-on clear circuit from operating:

- If the power lines of the microcomputer and EEPROM are separated from each other, and the output terminals of the microcomputer and EEPROM are wired or connected to each other, there may be a potential difference between the power lines of the EEPROM and microcomputer. If the voltage of the microcomputer is higher, a current may flow from the output terminal of the microcomputer to the power line of the EEPROM via a parasitic diode in the DO pin of the EEPROM. Therefore, the power voltage of the EEPROM has an intermediate potential to prevent power-on from being cleared.
- During an access to the EEPROM, the voltage may decrease due to power-off. Even if the microcomputer has been reset due to a decrease in voltage, the EEPROM may malfunction if EEPROM power-on clear operation conditions are not met. For the EEPROM power-on clear operation conditions, see "Method for Activating the Power Voltage."

Question:

False-writes in S-93C, S-29 series: inadvertent activation of CS (malfunction)

Answer:

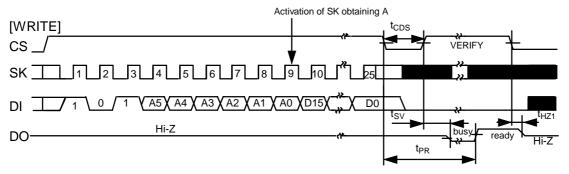

Inadvertent writing in the S-29 series

In the S-29 series, when a CS input is inadvertently activated during a write command, undefined data may be written. Relevant timings are shown below.

A command is composed of the following: "start bit + two command bits + address + (data)."

The figure below shows the timings in which commands are set (In the figure, the portion denotes the rising edge of SK.)

In the case of a write command, after a final address has been input and while 16-bit data is being input, undefined data is written when the CS input is changed from H to L.

<u>Case in which, during a command entry, CS is changed from H to L with a timing that differs by a predetermined minimum number of clocks.</u>

In the case of a write command, if the number of clocks is smaller than the predetermined value, data is loaded so as to be changed from D15 to D0. When, for example, CS is shifted from H to L after three clocks, data, which would otherwise have been stored in D15 to D13, is stored in D2 to D0, while undefined data is stored on the upper side a storage state in which the internal logic has been changed to either H or L). In addition, if the number of clocks is greater than the predetermined value, the last 16 pieces of data are stored correctly.

Question:

What about the basic terms (memory protect, reset, CS)?

Answer:

Memory protect, reset \rightarrow S-29xx1A, S-29x94A, S-29x55A

Function for prohibiting a write command from being executed in a certain region of the memory space. This function is enabled by controlling the protect or reset input pin (select/deselect protect). This reset prevents the microcomputer from running uncontrollably and also prevents false-writes caused by noise in order to protect data.

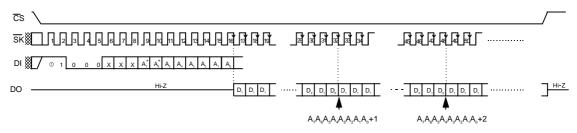

Ex.: Storage of ID codes and product shipment adjustment data

(Note) S-29xx1A and S-29x94A protect 50% of memory, starting with the leading address.

CS, /CS (/CS: S-29x55A, S-29x94A)

CS is an input pin used to select the execution of a command. It is selected using "H" and deselected using "L" (the reverse is true for /CS)

 \rightarrow /CS is useful on the interface of the microcomputer (L active is mainly used for the microcomputer). Malfunction, however, is likely to be caused by noise upon power-on if a command is executed at the GND level.

Question:

Concept of the compatibility, features, and markets of the S-29 series

Answer:

[Compatibility of the EEPROM]

In terms of memory, most SII EEPROMs are compatible with our competitors' standard products in their operation codes. If another company's product is to be replaced by a corresponding SII product, the DC/AC specifications desired by the user must be carefully determined.

The key words for the products are given below.

Our competitor's 93C-series products are compatible with SII's S-29xx0A-series products, and our competitor's 24C-series products are compatible with SII's S-24C-series products.

The key word for each company is given below.

- NM93C : National Semiconductor
- AT93C : ATMEL
- 93C : Microchip
- M93C : ST Micro electronic (formerly SGS Tomson ST93C)
- CAT93C : Catalyst
- AK93C : Asahi Kasei
- BR93C : ROHM

Question:

How are operation codes classified?

A:

[EEPROM operation codes]

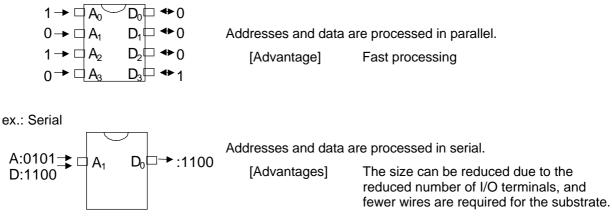

In the serial EEPROM, the operation codes can be classified into several types. Our competitors have released products compatible with each type of operation code. The key words of the operation codes are given below.

1. Serial and parallel

Data reading and writing are divided into serial and parallel types.

ex.: Parallel

The package can be downsized and manufactured inexpensively.

2. 3-wire type, microwire, 4-wire type

Composed of four pins, including three input pins CS, SK, and DI, and an output pin DO. Since DI and DO can be directly coupled together, the EEPROM can be virtually composed of three pins (the 4-wire type includes an additional Ready/Busy pin, but is still referred to as a "3-wire type").

① NS code: The key word is "93Cx." Compatible with SII S-29xxOA.

General code used by many competing companies. Mass produced and low in cost.

② GI code

General Instrument Inc.'s original code. Its markets continue to dwindle.

- ③ Mitsubishi code: The key word is "M6M8."Compatible with SII S-29x55A. Serial-port direct-coupling type in which commands and data are composed of x8 units. Intended for the TV and VTR markets and primarily sold as a set with Mitsubishi microcomputers.
- ④ SII original code: S-29x9xA

Serial-port direct-coupling type in which commands and data are composed of x8 units. Intended for technology-oriented users.

3. 2-wire type, IICBUS: The key word is "24C." Compatible with SII S-24CxxA. Composed of two pins: an input pin (SCL) and an I/O pin (SDA). Phillips Inc. owns a relevant patent.

[Advantages] Fewer wires are required, and the microcomputer port can be shared with another IICBUS. TV set maker will be main market.

4. SPI: The key word is "25C." Not compatible with SII. Under development. Composed of four pins: three input pins CS, SCK, and SI, and an input pin SO. In the case of the EEPROM, the advantages are high speed (5 MHz at 5v) and a high capacity (128 Kbytes).

Question:

What are the basic operation codes?

Answer:

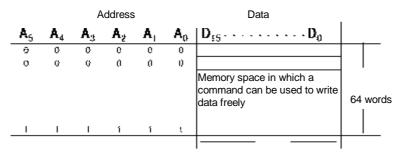

[Terms required to understand EEPROM data sheets (1)] Basic commands

- <u>Data read</u>, READ Reads data from a specified address
- <u>Data write</u>, WRITE or PROGRAM Writes data to a specified address
- <u>Data erase</u>, ERASE Erases data at a specified address (all "1"'s)
- <u>Chip write</u>, WRAL Writes the same (word) data in all address spaces
- <u>Chip erase</u>, ERAL Erases data in all address spaces (all "1"'s)
- <u>Program disable</u>, EWDS or PDS Prohibits write operations (WRITE), and prevents false-writes caused by noise or uncontrollable running of the CPU
- <u>Program enable</u>, EWES or PEN Enables write operations (WRITE)

[Note]

When the power to the EEPROM is turned on, the internal circuit of the IC is reset and the program disable mode is entered. Thus, following power-on, the program enable command must be entered in order to write data.

Memory space: In the case of the S-29130A (64 words X 16 bits)

16 bit

Question:

What about the basic terms. (continuous read, sequential read)?

Answer:

<u>Continuous read, sequential read</u> →S-93C series, S-29 series, S-24C series
 Function by which data is read from a specified address using a read command, followed by the output of the next address. This is useful when there is a large amount of user data (ex.: ID codes).

The serial port is a serial I/O port provided for a microcomputer. A device that can be easily and directly coupled to this port is referred to as a "serial-port direct-coupling type" or a "microcomputer interface."

- 1. The EEPROM is configured as follows for simple direct coupling:
- ① Data is input at the rising edge of the SK input clock, and output at its falling edge.
- ② Commands and data are input and output in 8 bits.
- 2. A microcomputer with a serial port communicates in 8 bits (8 clocks).

This configuration can substantially reduce the number of programs required for the microcomputer. The advantages are easy programming and a reduced ROM capacity.

Question:

What is the EEPROM?

Answer:

- 1. Electrically Erasable Programmable Read Only Memory
- Why this memory is referred to as "read only" despite the fact that it enables data to be rewritten? The EEPROM requires a longer time for writing than a RAM, so it is used exclusively for reading.
- What is the "memory"?
 Elements storing data. Data is generally represented by the digits "0" and "1."
- What is the "ROM"?
 Read Only Memory
 Reference: RAM is Random Access read write Memory.
