4 Mb/s Infrared Data Transceiver

FEATURES

- Compliant with IrDA Specification
- Data Rates 9.6 Kb/s to 4.0 Mb/s
- Wide Range of Supply Voltage 2.6 to 5.5 V
- Standby Current 3.3 mA at 5.0 V Typical
- Shut Down Current 0.01 μ A Typical
- Excellent Power Supply Noise Rejection
- Tri-State Receiver Output and TxD Disable
- AC Coupled Transmit Input
 - Provides Integrated Protection for Eye Safety
- High DC Ambient Rejection
- Independent LED Supply, Anode Pin Can Take
 - up to 9.0 V DC when not Transmitting and
 - up to 4.0 V above V_{CC} when Transmitting
- Receiver Latency Less than 100 μ s
- Slimline Package:
 - H 4.0 mm x D 4.8 mm x L 9.8 mm

DESCRIPTION

With state of the art submicron BiCMOS circuitry, coupled with Infineon optoelectronic expertise, the IRMS6400/IRMT6400 outperforms its closest rival. Infineon has incorporated a mode selection pin that toggles the device to operate in FIR (4 Mb/s) or SIR/MIR (9.6 Kb/s to 1.152 Mb/s) mode. Its external Shut Down (SD) feature cuts current consumption to typically 0.01 μ A. The transmit input is AC coupled, limiting transmit pulse duration to 70 μ s, preventing transmitter damage and continuous LED output. Mode select determines the data rate. Low for 9.6 Kb/s to 1.152 Mb/s, high for 4 Mb/s.

Note 1:

For Shut Down (SD) current to fall below $1\mu\text{A}$ requires driving the Shut Down (SD) pin to within 0.5 V of V_{CC} to ensure cutoff of the input PMOS transistor of the input CMOS totem pole.

Note 2:

Negative setup times indicate that the internal data propagation time is longer than the latching signal propagation time. This is common on logic devices. It means that the TxD data can go away before the negative Shut Down (SD) edge occurs and not lose the data. (See application notes for more details).

Note 3:

Shut Down (SD) to transmit enable is the time required for the transmit bias circuits to stabilize. Applying a transmit pulse before this time has elapsed will reduce the transmit pulse width.

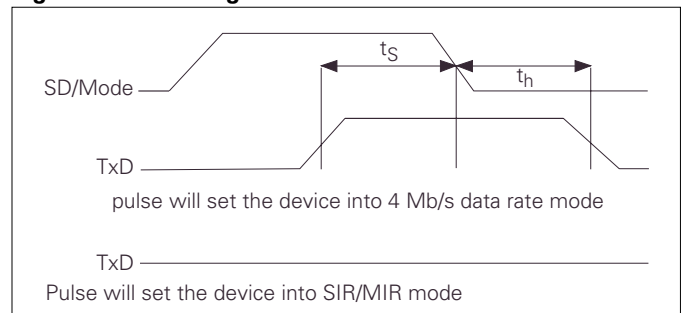

Note 4:

Transmit V_{CC} Transient Immunity measures the transmitter circuitry immunity from large V_{CC} and ground return inductive transients arising from the action of large transmitter di/dt currents on V_{CC} and ground return trace inductances. This test applies a negative 10 ns V_{CC} pulse to simulate the effects of transmitter current induce V_{CC} transients (assuming the LED anode supply and V_{CC} have a shared inductance) and measures for less than a 10% change in pulse width or delivered charge on the initial pulse and subsequent pulse.

Mode Switching (see Figure 2.)

Normally the IRMS6400/IRMT6400 Series initializes in the SIR/MIR (9.6 Kb/s to 1.152 Mb/s) mode upon power-up. Switching the module to FIR (4 Mb/s) Mode can be achieved as follows:

- Bring Shut Down (SD)/Mode pin to a logic "High" status.
- Bring TxD input to a logic "High" status. Wait for $t_s \geq -40\text{ ns}$.
- Bring Shut Down (SD)/Mode pin to a logic "Low" status. The negative transition of this pulse will set the module mode to (4 Mb/s) data rate by reading the state of TxD.
Bring TxD to a logic "Low" after waiting for $t_h \geq 90\text{ ns}$.

Figure 2. Switching Mode

Switching to SIR/MIR (9.6 Kb/s to 1.15 Mb/s) Mode:

- Bring Shut Down (SD)/Mode pin to a logic "High" status.
- Bring TxD input to a logic "Low" status. Wait for $t_s \geq -40\text{ ns}$.
- Bring Shut Down (SD)/Mode pin to a logic "Low" status. The negative transition of this pulse will set the module mode to 115 Kb/s data rate by reading the state of TxD.
